Lecture 31-32 – Outline

- Periodicity in transmission lines
- Resonances
- Standing waves and periodic oscillations
- Realization of reactance (inductance or capacitance) with short-circuited or with open-circuited transmission lines

Reading assignment
Prof. Kudeki’s ECE 329 Lecture Notes on Fields and Waves:
31) Periodic oscillations in lossless Transmission Line circuits
We mentioned last time that load location is the best space reference for steady-state analysis. We will explain why through examples.

Mathematically it’s the same as EM plane wave solution
Line with a generic load impedance

Since the reflection coefficient is

$$\Gamma_L = \frac{V_0^+}{V_0^-}$$

we can derive

$$V(d) = V_0^+ e^{j\beta d} \left(1 + \Gamma_L e^{-2j\beta d}\right) = V_0^+ e^{j\beta d} \left(1 + \Gamma(d)\right)$$

$$I(d) = \frac{V_0^+ e^{j\beta d}}{Z_0} \left(1 - \Gamma_L e^{-2j\beta d}\right) = \frac{V_0^+ e^{j\beta d}}{Z_0} \left(1 - \Gamma(d)\right)$$

$$\Gamma(d) = \Gamma_L e^{-2j\beta d}$$  \hspace{1cm} \text{generalized reflection coefficient}

$$Z(d) = \frac{V(d)}{I(d)} = Z_0 \frac{1 + \Gamma(d)}{1 - \Gamma(d)}$$  \hspace{1cm} \text{line impedance}
Significance of line impedance

Every line location is characterized by a line impedance $Z(d)$ and a reflection coefficient $\Gamma(d)$.

Imagine to cut the line at location $d$. The input impedance of the portion of line terminated by the load is the same as the line impedance at that location “before the cut”. The behavior of the line on the left of location $d$ is the same if an equivalent impedance with value $Z(d)$ replaces the cut out portion.
Periodicity of transmission lines

Consider monochromatic excitation of a transmission line at a specific frequency.

Let’s assume that we can change the length of the line, keeping the generator and the load unchanged (acoustic analogy: a slide trombone).

We will exclude the case of a load matched to the line’s characteristic impedance, since there are no reflections and the length does not affect the patterns of voltage and current.
Behavior of matched line \((Z_L = Z_0)\)

The current has a similar pattern along the line.
Line with arbitrary load  \( Z_0 = 50 \, \Omega \) and \( Z_L = 150 \, \Omega \)  \( l = 1.0 \, \lambda \)
Line with arbitrary load  \( Z_0 = 50 \, \Omega \) and \( Z_L = 150 \, \Omega \)  \( l = 2.38 \lambda \)
Line with arbitrary load \( Z_0 = 50 \, \Omega \) and \( Z_L = 150 \, \Omega \) \( l = 2.38 \, \lambda \)

Standing wave patterns

(Space-dependent magnitudes of the phasors for voltage and current)
Line with arbitrary load \( Z_0 = 50 \, \Omega \) and \( Z_L = 150 \, \Omega \) \( l = 2.38 \lambda \)

\[
\begin{align*}
\text{Re}\{Z(d)\} &= 150.0 \, \Omega \\
\text{Im}\{Z(d)\} &= 66.546 \, \Omega
\end{align*}
\]

\( d = 1.0 \lambda \)

Line impedance
Line with arbitrary load $Z_0 = 50 \, \Omega$ and $Z_L = 150 \, \Omega \quad l = 2.38 \, \lambda$

Reflection coefficient

$d = 1.0 \, \lambda$
Line with open circuit load  \( Z_0 = 50 \, \Omega \quad l = 0.5 \, \lambda \)
Line with open circuit load  \( Z_0 = 50 \, \Omega \quad l = 1.0 \, \lambda \)
Line with open circuit load \( Z_0 = 50 \ \Omega \quad l = 3.0 \ \lambda \)
Line with short circuit load \( Z_0 = 50 \, \Omega \) \quad l = 3.0 \lambda
short circuit load, open circuit input \[ Z_0 = 50 \, \Omega \quad l = 1.25 \, \lambda \]
These explorations show that periodicity of line properties are established by the reflection coefficient which repeats every $\lambda/2$.

For a given length of line we can identify resonant modes (complete standing waves) for frequencies which correspond to multiples of $\lambda/2$, when the ends of the line are both open circuits or short circuits.

\[ \omega = \frac{\pi v}{\ell} n \]
\[ f = \frac{v}{2\ell} n \text{ Hz} \]
\[ \lambda = \frac{v}{f} = \frac{2\ell}{n} \]

implying that resonances occur at frequencies for which the physical length corresponds to an integer number of $\lambda/2$.\[ \ell = n \frac{\lambda}{2} \]
Consider a line section open circuited at both ends. The current is expressed by forward and reflected waves as

\[ I(z, t) = \frac{f(t - \frac{z}{v})}{Z_o} - \frac{g(t + \frac{z}{v})}{Z_o} \]

with zero boundary conditions at the ends

\[ I(0, t) = \frac{f(t)}{Z_o} - \frac{g(t)}{Z_o} = 0 \quad \rightarrow \quad g(t) = f(t) \]

\[ I(l, t) = \frac{f(t - \frac{l}{v})}{Z_o} - \frac{g(t + \frac{l}{v})}{Z_o} = 0 \quad \rightarrow \quad f(t - \frac{l}{v}) = f(t + \frac{l}{v}) \]

period

\[ T = \frac{2l}{v} \]

fundamental frequency

\[ \omega_o = \frac{2\pi}{T} = \frac{\pi v}{l} \]
From Fourier analysis

\[ f(t) = F_0 + \sum_{n=1}^{\infty} F_n \cos(n\omega_o t + \theta_n) \]

with zero boundary conditions at the ends

\[ I(z, t) = \frac{f(t - \frac{z}{v}) - f(t + \frac{z}{v})}{Z_o} \]

\[ = \sum_{n=1}^{\infty} \frac{F_n}{Z_o} \left[ \cos(n\omega_o t + \theta_n - n\beta_o z) - \cos(n\omega_o t + \theta_n + n\beta_o z) \right] \]

\[ \beta_o \equiv \frac{\omega_o}{v} = \frac{\pi}{\ell} \]
In phasor form

\[
\tilde{I}(z) = \sum_{n=1}^{\infty} \frac{F_n}{Z_o} e^{j\theta_n} [e^{-jn\beta_0 z} - e^{jn\beta_0 z}]
\]

\[
= \sum_{n=1}^{\infty} \frac{F_n}{Z_o} e^{j\theta_n} (-2j) \sin(n\beta_0 z)
\]

Back to the time domain

\[
I(z, t) = \sum_{n=1}^{\infty} 2F_n \frac{2}{Z_o} \sin(n\omega_0 t + \theta_n) \sin(n\beta_0 z)
\]

\[
2 \sin(A) \sin(B) = \cos(A - B) - \cos(A + B)
\]

compare with original form
Similarly for the voltage

\[ V(z, t) = \sum_{n=1}^{\infty} 2F_n \cos(n\omega_o t + \theta_n) \cos(n\beta_o z) \]

from the phasor form

\[ \tilde{V}(z) = \sum_n F_n e^{j\theta_n} [e^{-jn\beta_0 z} + e^{jn\beta_0 z}] \]
Similarly for the voltage

\[ V(z, t) = \sum_{n=1}^{\infty} 2F_n \cos(n\omega_0 t + \theta_n) \cos(n\beta_0 z) \]

from the phasor form

\[ \tilde{V}(z) = \sum_n F_n e^{j\theta_n} [e^{-jn\beta_0 z} + e^{jn\beta_0 z}] \]
If the transmission line is terminated by a short circuit and has an open circuit on the other end then resonant frequency are obtained when the length $\ell$ corresponds to an odd multiple of $\lambda/4$

\[
\frac{\lambda}{4} = \frac{2\pi}{\beta} = \frac{\pi}{2\beta}
\]

resonant condition

\[
\ell = \frac{\lambda}{4} \left(2n + 1\right), \quad n \geq 0
\]

resonant frequency

\[
\omega = \frac{\pi v}{\ell} \left(\frac{1}{2} + n\right)
\]

for $n \geq 0$

\[
f = \frac{v}{2\ell} \left(\frac{1}{2} + n\right)
\]
Example

\[ \frac{\lambda}{4} \]

\[ 6 \times \frac{\lambda}{2} = 12 \times \frac{\lambda}{4} \]

open circuit

short circuit
Realize any imaginary impedance with a short-circuited line

\[ V(d = 0) = V_0^+ e^{j\beta_0} \left[ 1 + \Gamma_L e^{j2\beta_0} \right] = V_0^+ \left[ 1 + \Gamma_L \right] = 0 \]

\[ \Rightarrow \quad \Gamma_L = -1 \]

\[ \Gamma_L = \frac{V_0^+}{V_0^-} \quad \Rightarrow \quad V_0^- = -V_0^+ \]
short-circuited line

**line voltage**

\[
V(d) = V^+_0 e^{j \beta d} + V^-_0 e^{-j \beta d} = V^+_0 e^{j \beta d} - V^+_0 e^{-j \beta d} \\
= V^+_0 \left[ e^{j \beta d} - e^{-j \beta d} \right] = 2j V^+_0 \sin(\beta d)
\]

**line current**

\[
I(d) = \frac{1}{Z_0} \left[ V^+_0 e^{j \beta d} - V^-_0 e^{-j \beta d} \right] = \frac{1}{Z_0} \left[ V^+_0 e^{j \beta d} + V^+_0 e^{-j \beta d} \right] \\
= \frac{V^+_0}{Z_0} \left[ e^{j \beta d} + e^{-j \beta d} \right] = \frac{2V^+_0}{Z_0} \cos(\beta d)
\]

**line impedance**

\[
Z(d) = \frac{V(d)}{I(d)} = \frac{2j V^+_0 \sin(\beta d)}{2V^+_0 \cos(\beta d)/Z_0} = jZ_0 \tan(\beta d)
\]
Realize any imaginary impedance with an open-circuited line

\[ I(d = 0) = \frac{V_0^+}{Z_0} e^{j\beta_0} \left[ 1 - \Gamma_L e^{j2\beta_0} \right] = \frac{V_0^+}{Z_0} \left[ 1 - \Gamma_L \right] = 0 \]

\[ \Rightarrow \Gamma_L = 1 \]

\[ \Gamma_L = \frac{V_0^+}{V_0^-} \Rightarrow V_0^- = V_0^+ \]
open-circuited line

**line voltage**

\[ V(d) = V_0^+ e^{j \beta d} + V_0^- e^{-j \beta d} = V_0^+ e^{j \beta d} + V_0^+ e^{-j \beta d} \]

\[ = V_0^+ \left[ e^{j \beta d} + e^{-j \beta d} \right] = 2V_0^+ \cos(\beta d) \]

**line current**

\[ I(d) = \frac{1}{Z_0} \left[ V_0^+ e^{j \beta d} - V_0^- e^{-j \beta d} \right] = \frac{1}{Z_0} \left[ V_0^+ e^{j \beta d} - V_0^+ e^{-j \beta d} \right] \]

\[ = \frac{V_0^+}{Z_0} \left[ e^{j \beta d} - e^{-j \beta d} \right] = \frac{2j V_0^+}{Z_0} \sin(\beta d) \]

**line impedance**

\[ Z(d) = \frac{V(d)}{I(d)} = \frac{2V_0^+ \cos(\beta d)}{2 j V_0^+ \sin(\beta d)/Z_0} = -j \frac{Z_0}{\tan(\beta d)} \]
Reactive impedances can be realized with transmission lines terminated by a short or by an open circuit. The input impedance of a loss-less transmission line of length $L$ terminated by a short circuit is purely imaginary

$$Z_{in} = jZ_0 \tan(\beta L) = jZ_0 \tan\left(\frac{2\pi L}{\lambda}\right) = jZ_0 \tan\left(\frac{2\pi f}{v_p} L\right)$$

For a specified frequency $f$, any reactance value (positive or negative!) can be obtained by changing the length of the line from $0$ to $\lambda/2$. An inductance is realized for $L < \lambda/4$ (positive tangent) while a capacitance is realized for $\lambda/4 < L < \lambda/2$ (negative tangent).

When $L = 0$ and $L = \lambda/2$ the tangent is zero, and the input impedance corresponds to a short circuit. However, when $L = \lambda/4$ the tangent is infinite and the input impedance corresponds to an open circuit.
Since the tangent function is periodic, the same impedance behavior of the impedance will repeat identically for each additional line increment of length $\lambda/2$. A similar periodic behavior is also obtained when the length of the line is fixed and the frequency of operation is changed.

At zero frequency (infinite wavelength), the short circuited line behaves as a short circuit for any line length. When the frequency is increased, the wavelength shortens and one obtains an inductance for $L < \lambda/4$ and a capacitance for $\lambda/4 < L < \lambda/2$, with an open circuit at $L = \lambda/4$ and a short circuit again at $L = \lambda/2$.

Note that the frequency behavior of lumped elements is very different. Consider an ideal inductor with inductance $L$ assumed to be constant with frequency, for simplicity. At zero frequency the inductor also behaves as a short circuit, but the reactance varies monotonically and linearly with frequency as

$$X = \omega L \quad \text{(always an inductance)}$$
Short circuited transmission line – Fixed frequency

\[ L = 0 \quad Z_{in} = 0 \quad \text{short circuit} \]
\[ 0 < L < \frac{\lambda}{4} \quad \text{inductance} \]
\[ L = \frac{\lambda}{4} \quad Z_{in} \to \infty \quad \text{open circuit} \]
\[ \frac{\lambda}{4} < L < \frac{\lambda}{2} \quad \text{capacitance} \]
\[ L = \frac{\lambda}{2} \quad Z_{in} = 0 \quad \text{short circuit} \]
\[ \frac{\lambda}{2} < L < \frac{3\lambda}{4} \quad \text{inductance} \]
\[ L = \frac{3\lambda}{4} \quad Z_{in} \to \infty \quad \text{open circuit} \]
\[ \frac{3\lambda}{4} < L < \lambda \quad \text{capacitance} \]
Impedance of a short circuited transmission line (fixed frequency, variable length)

Normalized Input Impedance \( Z(L)/Z_0 = j\tan(\beta L) \)

- Inductive: \( \pi/(2\beta) = \lambda/4 \)
- Inductive: \( \pi/\beta = \lambda/2 \)
- Inductive: \( 3\pi/(2\beta) = 3\lambda/4 \)
- Inductive: \( 2\pi/\beta = \lambda \)
- Capacitive: \( 5\pi/(2\beta) = 5\lambda/4 \)

Line Length \( L \)

\( \theta \) [deg]
Impedance of a short circuited transmission line
(fixed length, variable frequency)

Normalized Input Impedance \( Z(L)/Z_0 = j \tan(\beta L) \)

- Inductive
- Capacitive

Frequency of operation:
- \( v_p / (4L) \)
- \( v_p / (2L) \)
- \( 3v_p / (4L) \)
- \( v_p / L \)
- \( 5v_p / (4L) \)

\( L = \text{Line length} \)

\( f \)
For a transmission line of length $L$ terminated by an open circuit, the input impedance is again purely imaginary

$$Z_{in} = -j \frac{Z_0}{\tan(\beta L)} = -j \frac{Z_0}{\tan\left(\frac{2\pi}{\lambda} L\right)} = -j \frac{Z_0}{\tan\left(\frac{2\pi f}{v_p} L\right)}$$

We can also use the open circuited line to realize any reactance, but starting from a **capacitive** value when the line length is very short.

Note once again that the frequency behavior of a corresponding lumped element is different. Consider an ideal capacitor with capacitance $C$ assumed to be constant with frequency. At zero frequency the capacitor behaves as an open circuit, but the reactance varies **monotonically** and **linearly** with frequency as

$$X = \frac{1}{\omega C} \quad \text{(always a capacitance)}$$
Open circuit transmission line – Fixed frequency

\[ L = 0 \]

\[ 0 < L < \frac{\lambda}{4} \]

\[ L = \frac{\lambda}{4} \]

\[ \frac{\lambda}{4} < L < \frac{\lambda}{2} \]

\[ L = \frac{\lambda}{2} \]

\[ \frac{\lambda}{2} < L < \frac{3\lambda}{4} \]

\[ L = \frac{3\lambda}{4} \]

\[ \frac{3\lambda}{4} < L < \lambda \]

\[ Z_{in} \to \infty \]

\[ \text{Im}\{Z_{in}\} < 0 \]

\[ Z_{in} = 0 \]

\[ \text{Im}\{Z_{in}\} > 0 \]

\[ Z_{in} \to \infty \]

\[ \text{Im}\{Z_{in}\} < 0 \]

\[ Z_{in} = 0 \]

\[ \text{Im}\{Z_{in}\} > 0 \]

open circuit

capacitance

short circuit

inductance

open circuit

capacitance

short circuit

inductance
Impedance of an open circuited transmission line
(fixed frequency, variable length)

Normalized Input Impedance $Z(L)/Z_0 = -j\cotan(\beta L)$

- Inductive regions:
  - $\pi/(2\beta) = \lambda/4$
  - $\pi/\beta = \lambda/2$
  - $3\pi/(2\beta) = 3\lambda/4$
  - $2\pi/\beta = 2\lambda$
  - $5\pi/(2\beta) = 5\lambda/4$

- Capacitive regions:
  - $0$
  - $100$
  - $200$
  - $300$
  - $400$
  - $500$

Line Length $L$

$\Theta \text{ [deg]}$
Impedance of an open circuited transmission line
(fixed length, variable frequency)

Normalized Input Impedance

\[ Z(L) / Z_0 = \frac{-j \cotan(\beta L)}{\beta L} \]

Frequency of operation

- \( v_p / (4L) \)
- \( v_p / (2L) \)
- \( 3v_p / (4L) \)
- \( v_p / L \)
- \( 5v_p / (4L) \)

\( L = \text{Line length} \)
You can also use

\[ Y_o \equiv \frac{1}{Z_o} \]  Characteristic admittance.

**Short circuited line**

**Input Impedance**

\[ Z(l) = jZ_o \tan(\beta l) \]

**Input Admittance**

\[ Y(l) = \frac{1}{Z(l)} = \frac{1}{jZ_o \tan(\beta l)} = -jY_o \cot(\beta l) \]
Resonant circuits

\[ \omega = \frac{1}{\sqrt{LC}} \equiv \omega_0 \]

Series

\[ Z_s = j(\omega L - \frac{1}{\omega C}) \]

short circuit at resonance

Parallel

\[ Y_p = j(\omega C - \frac{1}{\omega L}) \]

parallel circuit at resonance
A short line *stub* is equivalent to an **open circuit** when the length is an odd multiple of $\lambda/4$ with resonant frequencies

$$f = \frac{v}{2\ell} \left( \frac{1}{2} + n \right) \text{ for } n = 0, 1, 2, 3, \cdots$$

A short line *stub* is equivalent to a **short circuit** when the length is an even multiple of $\lambda/4$ (integer number of $\lambda/2$) with resonant frequencies

$$f = \frac{v}{2\ell} n \text{ for } n = 1, 2, 3, \cdots$$
You can build circuits with short TL stubs as reactive elements.

**Series network:**

**Parallel network:**
It is possible to realize resonant circuits by using transmission lines as reactive elements. For instance, consider the circuit below realized with lines having the same characteristic impedance:

\[ Z_{in1} = j Z_0 \tan(\beta L_1) \]
\[ Z_{in2} = j Z_0 \tan(\beta L_2) \]
The circuit is resonant if \( L_1 \) and \( L_2 \) are chosen such that an inductance and a capacitance are realized.

A resonance condition is established when the total input impedance of the parallel circuit is infinite or, equivalently, when the input admittance of the parallel circuit is zero

\[
\frac{1}{j Z_0 \tan(\beta_r L_1)} + \frac{1}{j Z_0 \tan(\beta_r L_2)} = 0
\]

or

\[
\tan\left(\frac{\omega_r}{v_p} L_1\right) = -\tan\left(\frac{\omega_r}{v_p} L_2\right) \quad \text{with} \quad \beta_r = \frac{2\pi}{\lambda_r} = \frac{\omega_r}{v_p}
\]

Since the tangent is a periodic function, there is a multiplicity of possible resonant angular frequencies \( \omega_r \) that satisfy the condition above. The values can be found by using a numerical procedure to solve the transcendental equation above.
